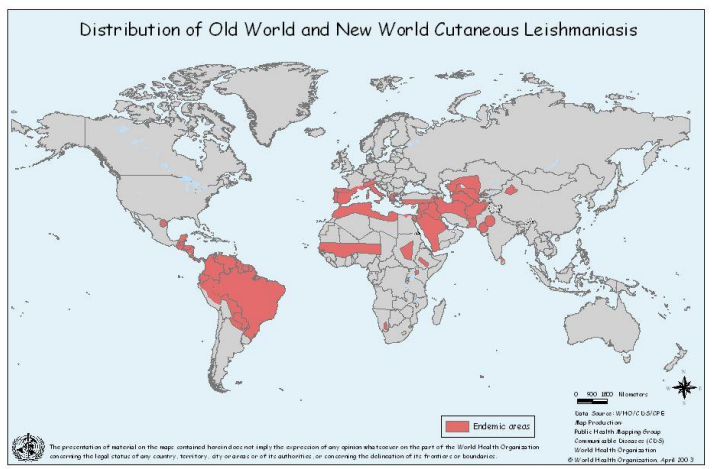
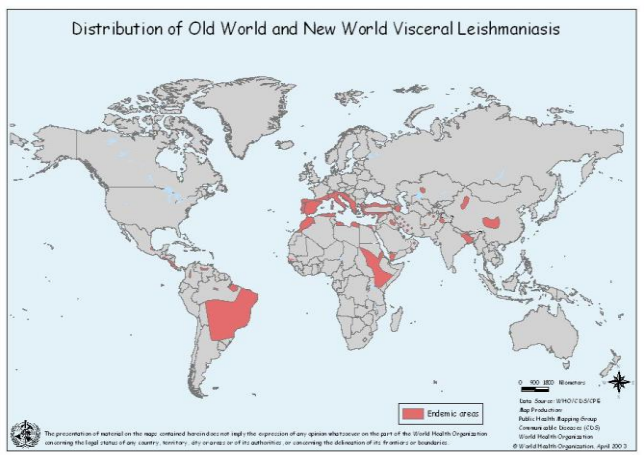
Leishmania and Leishmaniasis

Leishmaniasis





- World-wide disease: 88 countries

-Incidence per year: 1-1.5 million new cases of CL and 500 000 new cases of VL

-Population at risk: 350 millions

- Risk factors: urbanization, migration,

Extrinsic aspects

Why Leishmania typing is needed?

The use of biochemical and molecular methods increased our capacity to detected discreet differences among the *Leishmania* species and strains through diverse typing approaches. Such achievement, although positive, now raises the concern of which methodology to use from now on, and how to integrate the discoveries in a taxonomic way.

Regarding public health, now we ask how to gather all the methods available in order to provide an efficient and standardized diagnosis for leishmanisis.

There is an increasing demand for differential diagnosis to identify the infecting species, as prognosis of disease progression.

The *Leishmania* collection of the Oswaldo Cruz Institute (Coleção de *Leishmania* do Instituto Oswaldo Cruz), CLIOC, was created in 1980, with the support of the Oswaldo Cruz Institute, the Oswaldo Cruz Foundation and the World Health Organization.

CLIOC's mission is to act as a Biological Resource Center (as defined by the Organisation for Economic Cooperation and Development, OECD), dedicated to preservation, storage, distribution, taxonomic characterization, and identification of *Leishmania* and associated information, contributing to the scientific and technological development of the country. CLIOC attends public research and education institutions, industry in general, offering assistance and technical and scientific consultancy, Training and development of specific research projects. Its field of work is directly associated to collective health sectors of the country.

CLIOC is registered in the *World Federation for Culture Collections, WFCC* - WDCM 731 - and is recognized as a Depository Authority by the Ministry of the Environment [Fiel Depositária pelo Ministério do Meio Ambiente, MMA] (D.O.U. 05.04.2005).

The team of professionals and collaborators associated to CLIOC are qualified in parasitology, *Leishmania* systematics, with experience in molecular systematics, phylogeny, and in the use of culture independent methods to characterize *Leishmania* species associated to human diseases or that are found infecting other vertebrates and their vectors, phlebotomic insects.

CLIOC's holdings are limited to the different species of the genera *Leishmania*, pathogen to humans or not. Genetically modified organisms are accepted.

CLIOC maintains an information system about *Leishmania* holdings deposited in its collection.

Conclusions

- PCR-RFLP analysis of hsp70 has the potential to replace MLEE for *Leishmania* typing
- It thus present potential for direct diagnosis
- It is already used as an additional tool for *Leishmania* strain typing and characterization at the CLIOC routine.

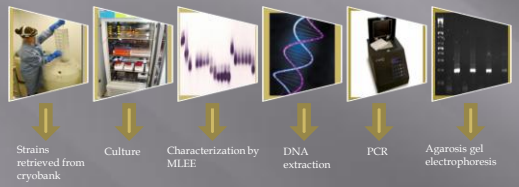
Testing and Validating PCR-RFLP of Heat-shock Protein 70 Gene for Further Use as a Universal Tool for Leishmania Identification and for Replacing MLEE

Mariana Côrtes Boité,Taíse Salgado de Oliveira, Barbara Neves dos Santos, Graziele Cardoso da Graça, Elisa Cupolillo

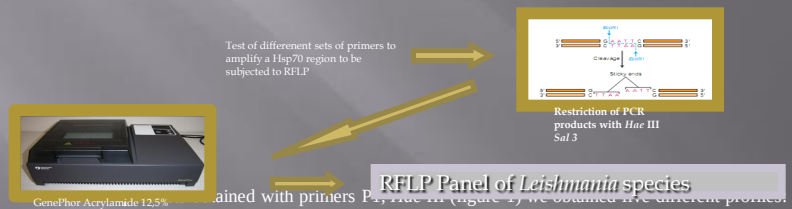
Laboratório de Pesquisa em Leishmaniose, Coleção de Leishmania do Instituto Oswaldo Cruz
IOC/FIOCRUZ, Instituto Oswaldo Cruz/Fundação Oswaldo Cruz, Av. Brasil 4365, Manguinhos, Rio de Janeiro, RJ, Brasil

In an attempt to overcome the limitations of multilocus enzyme electrophoresis (MLEE) - gold standard tool for *Leishmania* identification - PCR-based methods have been developed and employed. Studies performed by our group (da Silva et al., 2010) and colleagues (Montalvo et al., 2010) have demonstrated that the target hsp70 differentiates many New and Old World *Leishmania* species through PCR-RFLP and DNA sequencing. These findings suggest that such approach might represent a universal and accurate tool for *Leishmania* species identification. Based on that, we aim to validate hsp70 PCR-RFLP as a substitute for MLEE for *Leishmania* typing.

To construct a hsp70 PCR-RFLP panel we have used 17 reference strains, listed below, representing *Leishmania* species of the New and Old World, from CLIOC – Oswaldo Cruz Institute Collection. The methodology followed the flux as follows:



One pair of primers and PCR conditions were the same from a previous study (da Silva et al., 2010). However, for the present project we included two more pair of primers to be tested, which amplify smaller products. The DNA was properly amplified for each set of primers and the fragments observed in 1% agarose gels to check PCR effiency. Hsp70 PCR products were digested with *Hae*III and *Sau* 3. Products were subjected to 12.5% acrylamide gel electrophoresis (Genephor) and also to conventional acrylamide 6% gel and then silver stained.



ained with primers P1, Hae III (figure 1) we obtained five different profiles: one only observed just in *L. guyanensis*, one for *L. donovani*, *L tropica* and *L. infantum syn. chagasi*, one for *L. braziliensis* and *L. naiffi*; one for *L. shawi*, *L. lainsoni* and *L. hertigi*. The other species did not present any restriction site for the enzyme (same profile from the non digested produtc (NDP). In figure 2 we also observed five profiles, and in this case *L. mexicana*, *L. tropica* and *L. donovani* complexes could not be distinguished, but *L. major* complex, as well as the Paraleishmania, could be differentiated for the other species. For the L. (Viannia) species this combination was not able to differentiate *L. guyanensis* and *L. shawi*, as well as *L. braziliesis*, *L. lainsoni* and *L. naiffi*.

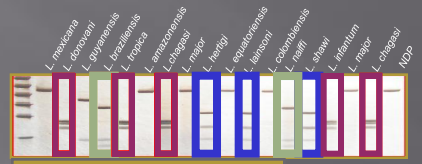


Figure 1: P1 PCR products, enzyme *Hae* III

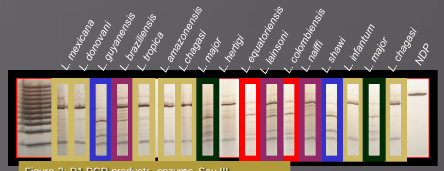

Figure 2: P1 PCR producrt, enzyme *Sau* III

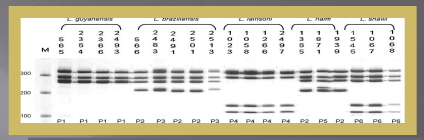

Figure 3: Previous results with PCR product 1400bp and *Hae* III

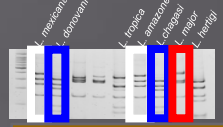

Figure 4: PCR product 1400bp and *Hae*III in a 6% acrylamide gel

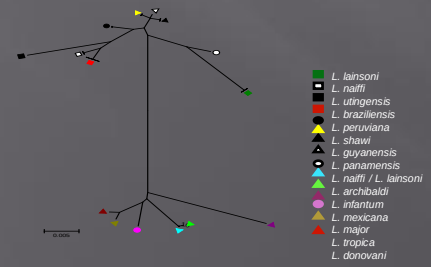
Using the same set of primers from a previous study of our group (figure 3) we could reinforce the potential of Hsp70 marker as a target to differentiate New and Old Wolrd *Leishmania* species (figure4). In the first study, species of *L. (Viannia)* could be differentiated. Now we aim to increase the number of species studied, therefore species from subgenera *L. (Leishmania)* were included. The figure 4 shows a conventional 6% acrylamide gel, which was prepared in order to test the viability of its use for the present purpose, since Genephor® in a more expensive methodology. *L donovani*, *L. mexicana* and *L. major* complexes could be differentiated. However species from the same complex could not be distinguished.



40 Hsp70 DNA sequences available in Genbank (http://www.ncbi.nlm.nih.gov/) of 14 different *Leishmania* species were aligned in MEGA software and a Neighbor Joining tree was obtained. The tree shows that the target Hsp70 presents an interesting degree of polymorphism between species, which allows clear separation of subgenera and species.

Studies performed targeting Hsp70 found it as good single locus way to distinguish between *Leishmania* species. However, more tests must be applied in order to construct a final panel to be compared between laboratories and to extend the usefulness of this approach to, for instance, direct diagnosis of the disease.
